Art Unit: 2122

DETAILED ACTION

1. This action is in response to Amendment A, filed 1 March 204. Per Applicant's request, claims 8, 17, and 18 have been amended. Claims 1-19 are pending

Priority

2. Acknowledgment is made of the receipt of certified copy of the UK Patent Application as required by 35 U.S.C. 119(b), on 1 March 2004.

Specification

- Applicant is reminded to provide Cross-References to Related Applications (See 37
 CFR 1.78 and MPEP § 201.11.)
- 4. In view of Applicant's comments, the objection to the disclosure on page 5, lines 25-29 repeat the previous paragraph is hereby withdrawn.

Claim Objections

5. In view of the amendments to claims 17 & 18, the objections in the prior Office Action are hereby withdrawn.

Claim Rejections - 35 USC § 112

- 6. The following is a quotation of the second paragraph of 35 U.S.C. 112:
 The specification shall conclude with one or more claims particularly pointing out and distinctly claiming the subject matter which the applicant regards as his invention.
- 7. Regarding claims 8 and 9, in view of the amendment to claim 8, the former rejection of claims 8 and 9 is hereby withdrawn.

Regarding claim 16, the phrase "...software interpreter is stored within said cache memory both when executing native program instruction words and interpreted program instruction words." It would be clearer if the phrase recited, "...software interpreter is stored

Art Unit: 2122

within said cache memory when both native program instruction words and interpreted program instruction words are executing." The former phrase implies that the interpreter executes native program instruction words, and is thus unclear.

Claim Rejections - 35 USC § 102

(e) the invention was described in (1) an application for patent, published under section 122(b), by another filed in the United States before the invention by the applicant for patent or (2) a patent granted on an application for patent by another filed in the United States before the invention by the applicant for patent, except that an international application filed under the treaty defined in section 351(a) shall have the effects for purposes of this subsection of an application filed in the United States only if the international application designated the United States and was published under Article 21(2) of such treaty in the English language.

8. Claims 1 – 5, 8, and 19 are rejected under 35 U.S.C. 102(e) as being anticipated by US Patent 6,513,156 to Bak.

Per claims 1 and 19:

-a processing unit responsive to native program instruction words to perform data processing operations; (Fig. 5. Col. 8, lines 1-2, "hybrid virtual and native machine instructions...")
-an instruction interpreter responsive to one or more interpreted instruction words specifying a data processing operation to execute native instruction words upon said processing unit to perform said data processing operation; (Col. 8, lines 7-10, "The interpreter generates modified JAVA virtual machine instructions by overwriting bytecode with a go_native virtual machine instruction.")

-a memory for storing said computer program wherein... (Fig. 2, and col. 4, lines 47-50, "...system memory...to store and retrieve software...that implements the invention...")
-said computer program includes both native instruction words and interpreted instruction words; (Fig. 5. Note native instructions in 'SNIPPET ZONE', interpreted instructions in 'MODIFIED JAVA VIRTUAL MACHINE INSTRUCTIONS'. Solid arrow indicates program switch to native instructions and dashed arrow indicates program return to interpreted instructions.)

Art Unit: 2122

-a native code portion invokes interpretation of an interpreted code portion by executing a native code call instruction to said instruction interpreter; -execution of said native code call instruction triggers generation of a return address specifying a location within said memory for said native code call instruction; -said instruction interpreter uses said return address as a pointer to said interpreted code portion within said memory. (Fig. 11 and col. 12, lines 13-17, "Once the virtual function finishes execution (native code finishes), the system returns to the return address that was pushed on the stack at step 907. At the return address, there are native machine instructions for the interpreter to reload the saved bytecode pointer...")

Per claim 2:

-return address is an address immediately succeeding an address of said native code call instruction within said memory. (See fig. 5, and col. 8, lines 36-39, "The native machine instructions in the snippet perform the same operations as if the bytecodes 2-5 would have been interpreted. Afterwards, the interpreter continues with the execution of bytecode 6 as if no snippet existed.")

Per claim 3:

-instruction interpreter writes a new value of said return address for use by a native code return instruction as a pointer to a next native code instruction to be executed when interpretation of said interpreted code portion is finished and return is being made to execution of said next native code portion of said computer program. (When snippet finishes and returns to interpreter, the interpreter may have a successive go_native instruction pointing to a second snippet. See figure 13. Any number of native code snippets may be stored. A virtual machine go_native instruction references the snippets.)

Page 5

Art Unit: 2122

Per claim 4:

-interpreted code portion finishes with an interpreted return instruction that returns execution to a native code portion at an address pointed to by said return address. (Col. 8, lines 32-35, "When the interpreter executes the go_native bytecode, the interpreter will look up the snippet in the snippet zone specified by the go_native bytecode and then activate the native machine

Per claim 5:

instructions in the snippet.")

-interpreted code portion finishes with an interpreted exit instruction that results in execution of a next native code portion stored within said memory at an address immediately following said exit instruction without a return being made corresponding to said native code call instruction.

(See figure 13, interpreter code followed by exit instruction (go_native instruction), results in execution of native code.)

Per claim 8:

- a majority of interpreted code instruction words corresponds to a native code instruction word. (See fig. 5 and col. 3, lines 5-8, "The new virtual machine instruction may include a pointer to a data block in which is stored the native machine instructions, the copy of the selected virtual machine instruction (correspond)..." At col. 2, lines 32-33, Bak noted, "embodiments of the present invention provide...for increasing the execution speed of computer programs...", Col. 6, lines 61-66, "A portion of the virtual machine instructions of the function are selected to be compiled at step 203 (FIG. 4). Typically, the system recognizes individual bytecodes or sequences of bytecodes that may be advantageously compiled. For example, the system may generate a snippet for each JAVA invoke_virtual bytecode (majority of interpreted code

Art Unit: 2122

instruction words) that is encountered...")

Claim Rejections - 35 USC § 103

- 9. The following is a quotation of 35 U.S.C. 103(a) which forms the basis for all obviousness rejections set forth in this Office action:
 - (a) A patent may not be obtained though the invention is not identically disclosed or described as set forth in section 102 of this title, if the differences between the subject matter sought to be patented and the prior art are such that the subject matter as a whole would have been obvious at the time the invention was made to a person having ordinary skill in the art to which said subject matter pertains. Patentability shall not be negatived by the manner in which the invention was made.
- 10. Claims 6, 7, and 10-13 are rejected under 35 U.S.C. 103(a) as being unpatentable over US Patent 6,513,156 to Bak et al., in view of US Patent 6,081,665 to Nilsen et al. Per claims 6 and 7:

Bak disclosed the use of a hybrid system that processed both bytecode and native machine instructions for the purpose of increasing execution efficiency. Bak disclosed (col. 12, lines 6-22), "The system pushes the interpreter return address on the stack...The interpreter return address is a predefined location where the execution of the interpreter...should resume. The native machine instructions...instruct the system to jump to the function specified...Once the virtual function (the native instructions) finishes...the system returns to the return address that was pushed on the stack...At the return address, there are native machine instructions for the interpreter to reload the saved bytecode pointer...so the interpreter may continue where it left off..." Bak failed to discuss the register storage as used by executing native instructions. However, Nilsen disclosed a "Processing unit includes a bank of data processing registers and said return address is stored within a predetermined data processing register within said bank of data processing registers upon execution of said native code call instruction." And "-memory

Art Unit: 2122

includes a stack memory region and said return address is copied from said predetermined data processing register to said stack memory region upon invocation of said interpreted code portion."

(See fig. 94, saved registers. Also, col. 17, line 44 describes the processes that are implemented when bytecode is called. Col. 18, line 45, describes the processes that are implemented when native instructions are called. "Copies the register-held psp and npsp registers into global memory locations...Then assigns sp and fp (the machine's stack and frame pointer registers) to reflect the current c-stack context...Copies the return address of the non-pointer stack and saves its value...")

Therefore, it would have been obvious, to one of ordinary skill in the art, at the time of the invention, to have modified Bak's disclosed invention that processes native and bytecode instructions, by including information regarding the register storage as well as the stack storage, because it is well known that a virtual machine is a stack machine, storing needed values on the stack, and it is well known that a processor for native instructions frequently has a register based architecture, and as processing switches from one instruction set to the other, some technique is necessary to copy values from the register based machine to the stack based machine and viceversus.

Per claims 10-13:

Bak disclosed the use of a hybrid system that processed both bytecode and native machine instructions. Bak failed to discuss the bit size of native code instruction words and interpreted code instruction words and the bit size of the data processing operations to be performed.

Art Unit: 2122

However, Nilsen disclosed, "Byte code is a term of art that describes a method of encoding instructions (for interpretation by a virtual machine) as 8-bit numbers, each pattern of 8 bits representing a different instruction" (col. 3, lines 29-32). Also, col. 12, lines 23-24, "The...virtual machine consists primarily of an interpreter for the ...byte-code instruction set..." and lines 40-50, "'The...programmer can choose to implement certain methods in C (frequently 32 bit instructions). At run-time, these methods are represented by native machine code...All other PERC methods are written in PERC. At runtime, certain methods written in PERC are represented as PERC byte codes (8 bit instructions)..." Additionally, Nilsen disclosed that both native code instruction words and interpreted code instruction words specify N-bit data processing operations to be performed, as an example (col. 8, lines 45-64, "...the signature structure used to represent the memory layout of heap-allocated objects...When the garbage collector (used with bytecode execution) scans the corresponding object in search of pointers, it looks no further than the word numbered last_descriptor.type_code comprises a 2 bit type tag...with the remaining 30 bits representing the value..." Furthermore, ultimately all byte code instructions (8 bit) map to native instructions (could be 32 bits) for processing.

Therefore, it would have been obvious, to one of ordinary skill in the art, at the time of the invention, to have considered that native code instruction words (which can have 32 bits) have more bits than interpreted code words (bytecodes of 8 bits) and that a 32 bit architecture processing bytecode, using a virtual machine, ultimately maps each processing operation to the 32 bit architecture. Virtual machines processing 8-bit bytecode hosted on a 32-bit processor are well known in the art, and thus inherent.

Art Unit: 2122

11. Claim 9 is rejected under 35 U.S.C. 103(a) as being unpatentable over US Patent 6,513,156 to Bak et al.

Per claim 9, "native code instruction words form a native code instruction set and said interpreted code instruction words form an interpreted code instruction set, data processing operations provided by said interpreted code instruction set being a subset of data processing operations provided by said native code instruction set."

It is well known that a virtual machine / interpreter hosted on a native machine interprets instructions that are ultimately mapped to machine code of the host machine. Therefore, it is inherent that the virtual machine / interpreter uses a subset of instructions of the host machine instruction set.

12. Claims 14-18 are rejected under 35 U.S.C. 103(a) as being unpatentable over US Patent 6,513,156 to Bak et al., in view of US Patent Application 2003/191792 to Waki et al. (April 1999).

Per claims 14-16, Bak disclosed the use of a hybrid system that processed both bytecode and native machine instructions. Bak failed to disclose that the interpreter is formed of native code instruction words, and can be stored in cache memory for the duration of executing native program instruction words and interpreted program instruction words.

However, Waki disclosed, at page 13, paragraph [0248], "The virtual machine (an interpreter) and the virtual machine compiler of the present embodiment are programs written with instructions for the real machine (native code)." Per claims 15 and 16, Waki disclosed, "cache memory and wherein said software interpreter is, in use, stored within said cache memory." At page 5, paragraph [0078], "...sample virtual machine program shown in Fig. 27 is

stored in the cache memory..." Also, page 6, paragraph [0085], "...a high speed virtual machine system that can be used by a real machine with a cache system..."

Therefore, it would have been obvious, to one of ordinary skill in the art, at the time of the invention, to have included details on the interpreter formed of native code instruction words and allow for the possibility of storing the interpreter in cache because the host machine must be able to process the interpreted instructions therefore they must be in the host machine language and an interpreter, a running program, located in a cache, provides a high speed memory location, allowing for more efficient execution.

Per claims 17 and 18, Bak disclosed the use of a hybrid system that processed both bytecode and native machine instructions. Bak failed to disclose information regarding execution frequency and speed in making choices between using compiled native code versus using interpreted bytecode.

However, Waki disclosed execution speed and execution frequency are considerations when deciding which parts of the code to leave as bytecode to be interpreted (slower) and which parts of the code to process as native code (faster) at page 2, paragraph [0021], "...how to increase execution speed..." and at page 3, paragraph [0026], "...execution speed being increased in proportion to the reduction in the number of memory accesses (frequency)..." Page 3, paragraph [0028] discusses a "...predetermined part of the virtual machine program is written in real machine instructions..." showing that some consideration is given to which parts will execute more efficiently in native code. At page 7, paragraph [0096], "...replace...stack operations (used in virtual machine byte code interpreting)...with read/write operations for the internal registers (used in native code processing) ...execution efficiency of the virtual machine

Art Unit: 2122

is raised." At page 8, paragraph [0114], "...control switches between executing a virtual machine function and a real machine function...improved execution speed..." Page 10, paragraph [0133], "...the present invention improves execution speed...promote efficient and high-speed use of shared resources..." Additionally, Waki considers the frequency on interrupt handling (page 8, paragraph [0108]) to avoid decreases in execution speed.

Therefore, it would have been obvious, to one of ordinary skill in the art, at the time of the invention, to have included information regarding improved efficiency, considering execution speed and execution frequency, because this is the purpose of modifying byte code to native code.

Response to Arguments

13. Applicant's arguments filed in Amendment A, 1 March 2004, have been fully considered but they are not persuasive.

(A) Applicant has argued, in substance, the following:

Page 12, 5th paragraph, of Amendment A, the cited art, Bak, US Patent 6,513,156 "describes the opposite of what is recited in element (v) of claim 1. Bak's interpreted code is invoking a native code portion" in contrast to the language of claim 1, "a native code portion invokes interpretation of an interpreted code portion."

Examiner's Response:

Art Unit: 2122

Bak's invention alternates between interpreted code and native code. See FIG. 5 and response to claim 1 above. Thus interpreted and native are both invoked in the executing program.

Page 12

(B) Applicant has argued, in substance, the following:

Page 13, 2nd paragraph, of Amendment A, the cited art, Bak, US Patent 6,513,156, fails to disclose "triggering, in response to the native code call instruction, generation of a return address specifying a location within said memory for said native code call instruction, where said instruction interpreter uses said return address as a pointer to said interpreted code portion within said memory."

Examiner's Response:

Bak, Figure 1 and column 12, lines 13-17 are referenced. Col. 3, lines 63-64, "FIG. 11 shows a process of executing snipped code (native code) for the invoke_virtual bytecode." Col. 12, beginning at line 1, describes the "system (native) saves the current bytecode pointer", by pushing the return address on the stack. A return address is generated, in response to a trigger.

(C) Applicant has argued, in substance, the following:

Page 13, 2nd paragraph, of Amendment A, "Bak does not specify that the virtual function itself is replaced by native code."

Examiner's Response:

Art Unit: 2122

In response to applicant's argument that the references fail to show certain features of applicant's invention, it is noted that the features upon which applicant relies (i.e., Applicant argues, "Bak does not specify that the virtual function itself is replaced by native code") are not recited in the rejected claims. Although the claims are interpreted in light of the specification, limitations from the specification are not read into the claims. See *In re Van Geuns*, 988 F.2d 1181, 26 USPQ2d 1057 (Fed. Cir. 1993).

(D) Applicant has argued, in substance, the following:

Page 13, end of 2nd paragraph, of Amendment A, the cited art, Bak, US Patent 6,513,156 "generating the address of the virtual function to be executed is performed at the compilation stage (enabling hard coding of the address) rather than at execution of a native code call as recited in claim 1.

Examiner's Response:

In response to applicant's argument that the references fail to show certain features of applicant's invention, it is noted that the features upon which applicant relies (i.e., Applicant argues, "generating the address of the virtual function to be executed is performed at the compilation stage (enabling hard coding of the address) rather than at execution of a native code call") are not recited in the rejected claims. Although the claims are interpreted in light of the specification, limitations from the specification are not read into the claims. See *In re Van Geuns*, 988 F.2d 1181, 26 USPQ2d 1057 (Fed. Cir. 1993).

Art Unit: 2122

Generating a return address does not exclude "reading a saved bytecode pointer from memory so the interpreter may continue where it left off." The claim is not specific regarding how the return address is generated, only that generation is triggered in response to execution of a native code call.

Examiner maintains the rejection of claims 1-19.

Conclusion

14. The prior art made of record and not relied upon is considered pertinent to applicant's disclosure.

US Patent 6,151,703 to Crelier (See column 10, program execution calls from interpreted code as well as compiled code.)

US Patent 6,298,434 to Lindwer (Preprocessor fetches virtual machine instructions & generates native instructions.)

US Patent 6,564, 241 to Rosengard (Interpreter stored within cache memory.)

15. THIS ACTION IS MADE FINAL. Applicant is reminded of the extension of time policy as set forth in 37 CFR 1.136(a).

A shortened statutory period for reply to this final action is set to expire THREE MONTHS from the mailing date of this action. In the event a first reply is filed within TWO MONTHS of the mailing date of this final action and the advisory action is not mailed until after the end of the THREE-MONTH shortened statutory period, then the shortened statutory period will expire on the date the advisory action is mailed, and any extension fee pursuant to 37

Art Unit: 2122

Page 15

CFR 1.136(a) will be calculated from the mailing date of the advisory action. In no event, however, will the statutory period for reply expire later than SIX MONTHS from the mailing date of this final action.

Any inquiry concerning this communication or earlier communications from the 16. examiner should be directed to Mary Steelman, whose telephone number is (703) 305-4564. The examiner can normally be reached Monday through Thursday, from 7:00 A.M. to 5:30 P.M. If attempts to reach the examiner by telephone are unsuccessful, the examiner's supervisor, Tuan Dam can be reached on (703) 305-4552.

The fax phone number is (703) 872-9306 for regular communications and for After Final communications. Any inquiry of a general nature or relating to the status of this application or proceeding should be directed to the receptionist whose telephone number is (703) 305-3900.

May Shilman
